School-based anthropometric observations represent a potential approach to address children and their families to correct life habits.

On October 2007, weights and standing heights of 261 6yr-old primary school children (116 girls; 145 boys) in Voghera (Pavia, Italy) were measured, and Body Mass Indices (BMI) calculated. Measurements were repeated 1 and 2 years later. Descriptive statistics of each parameter were computed within sex and session (Tab. 1). Comparisons were performed by ANOVA (F1, factor 1, sex; F2, factor 2, age; F1×F2 interaction). Statistical significance was set at $5 \%$ for all comparisons. Within age, the distributions and the percentages of boys and girls relatively under- ( $<3^{\text {rd }}$ percentile), and overweight $\left(>97^{\text {th }}\right.$ percentile) were computed (Tab. 1), while comparing BMI to reference data for Italian children (Cacciari et al., 2002).

|  | Girls |  |  |  |  | Boys |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\mathbf{6 ~ y r}$ | $\mathbf{7 ~ y r}$ | $\mathbf{8 ~ y r}$ | $\mathbf{6 ~ y r}$ | $\mathbf{7 ~ y r}$ | $\mathbf{8 ~ \mathbf { ~ y r }}$ |  |  |  |
| Weight $\mathbf{( k g})$ | $23.5 \pm 4.3$ | $26.2 \pm 5.1$ | $30.6 \pm 11.8$ | $24.9 \pm 5.0$ | $27.7 \pm 6.1$ | $31.1 \pm 7.5$ |  |  |  |
| Height $(\mathbf{c m})$ | $120.2 \pm 6.1$ | $124.6 \pm 6.2$ | $129.8 \pm 11.8$ | $121.1 \pm 6.0$ | $125.7 \pm 6.1$ | $131.8 \pm 6.2$ |  |  |  |
| BMI $\left(\mathbf{k g} / \mathbf{m}^{2}\right)$ | $16.2 \pm 2.4$ | $16.8 \pm 2.7$ | $18.8 \pm 12.1$ | $16.8 \pm 2.4$ | $17.4 \pm 2.8$ | $19.0 \pm 5.9$ |  |  |  |
| BMI $<\mathbf{3}^{\text {rd }}$ | $5(4.3)$ | $7(6.0)$ | $13(11.2)$ | $5(3.4)$ | $4(2.8)$ | $6(4.1)$ |  |  |  |
| BMI $>\mathbf{9 7}^{\text {th }}$ | $2(1.7)$ | $3(2.6)$ | $7(6.0)$ | $10(6.9)$ | $10(6.9)$ | $8(5.5)$ |  |  |  |

Tab. 1. Descriptive statistics (mean $\pm$ SD) of anthropometric variables at different ages. Distributions and (percentages) of boys and girls relatively under- and overweight.

On average, weight, height, and BMI were larger in boys than in girls, but the differences were not significant ( $\mathrm{F} 1, \mathrm{p}>0.05$ ). Boys and girls significantly grew with age ( F 2 , $\mathrm{p}<0.001$ for all comparisons). The effects of age on height increments were larger in boys than in girls ( $\mathrm{F} 1 \times \mathrm{F} 2$ interaction, $\mathrm{p}=0.017$ ). In boys, BMI was too high in a larger percentage than in girls. Conversely, the percentage distribution of participants whose BMI was too law was larger in girls than in boys, and increased with age.

The study allowed the monitoring of growth in school children during a 3yr life span. Further investigations on this matter should be extended to different age groups of children and adolescents, and prolonged as much as possible.
